

Distribution network low-carbon operation solar container energy storage system

Overview

To address these complexities, this paper introduces a two-stage model for reconfiguring distribution networks and ensuring low-carbon dispatch. Initially, second-order cone programming is employed to minimize losses in the network. Subsequently, the outputs of renewable energy and energy storage. Under the “dual carbon” goals, virtual energy storage (VES) resources present new opportunities for low-carbon planning in distribution networks. This paper, therefore, proposes a low-carbon planning method for distribution networks that comprehensively considers VES resources, renewable energy. By considering the impacts of carbon costs and electricity price signals, a strategy for energy storage charge and discharge is proposed with the dual objectives of maximizing economic benefits and minimizing carbon emissions. Finally, the effectiveness of the proposed model is validated through.
